

AWS S3 Lab: Creating a Bucket & Loading Data for DataBrew

LAB OVERVIEW

Create an Amazon S3 bucket and organize it with folders and sample data files. This bucket will serve as the data source for AWS DataBrew data cleaning exercises.

STEP-BY-STEP PROCEDURES

STEP 1: Access Amazon S3

- In AWS Management Console, search for "S3"
- Click on S3 to go to the landing page

STEP 2: Create the S3 Bucket

- Click "Create bucket" button (right side of page)
- **Bucket Name:** `databrew-data-lab-[UNIQUE-STRING]`
 - Note: Each bucket name must be globally unique across all AWS accounts and regions
- Leave all other settings as default
- Scroll to bottom and click "Create bucket"

STEP 3: Create Root-Level Folders

- Click the bucket name to enter it
- Click "Create folder"
- Create three folders with these exact names:
 1. **raw-data** (stores data files)
 2. **cleaned-data** (stores DataBrew output)
 3. **recipes** (stores DataBrew transformation recipes)

STEP 4: Upload Raw Data Files to raw-data Folder

- Navigate into the **raw-data** folder
- Click "Upload"
- Upload the `employee_data.csv` file using either:
 - Drag and drop into the upload area, OR
 - Click "Add files" and select the file
- Verify the file appears in "Files and folders" list
- Click "Upload"

- Wait for green "Upload succeeded" banner
- Click "Close"

STEP 5: Verify Bucket Structure

- Navigate back to bucket root
- Verify all three folders exist:
 - ✓ raw-data (with employee_data.csv inside)
 - ✓ cleaned-data (empty, ready for DataBrew output)
 - ✓ recipes (empty, ready for transformation recipes)

FINAL BUCKET STRUCTURE

databrew-data-lab-[UNIQUE-STRING]/

```
|— raw-data/  
|   |— employee_data.csv  
|— cleaned-data/  
|— recipes/
```

KEY DELIVERABLES

- ✓ S3 bucket created with unique name
- ✓ Three root folders created: raw-data, cleaned-data, recipes
- ✓ employee_data.csv uploaded to raw-data folder
- ✓ Cleaned-data folder ready to receive DataBrew outputs
- ✓ Recipes folder ready to store transformation rules

IMPORTANT NOTES

- S3 bucket names must be unique globally across all AWS accounts and regions
- Folder structure is organized for DataBrew workflow:
 - **raw-data**: Where source data lives
 - **cleaned-data**: Where DataBrew will save cleaned outputs
 - **recipes**: Where DataBrew stores transformation rules (optional but recommended)
- Bucket should be in the same AWS region as DataBrew for best performance

WHY THIS BUCKET STRUCTURE FOR DATABREW?

- **raw-data folder**: Keeps original messy data separate and unchanged
- **cleaned-data folder**: Organizes all DataBrew outputs in one location
- **recipes folder**: DataBrew can save transformation recipes for reuse on similar datasets
- **Clear separation**: Makes it easy to track data lineage and understand transformations applied
